CASE STUDY 1

Truss Joint Force Analysis

Introduction:

Structural systems composed of axially loaded members are fundamental in mechanical and structural engineering applications such as machine frames, support structures, space frames, and load-bearing assemblies. A truss is an idealized structural system in which members are connected by frictionless pin joints and carry only axial forces (tension or compression).

In this case study, a planar two-dimensional truss subjected to static external loads is analysed using the **Direct Stiffness Method (Global Stiffness Matrix Method)**. The governing equilibrium equation of the structure is expressed in matrix form as:

$$[K][U] = [F]$$

where:

K = Global stiffness matrix

U = Nodal displacement vector

F = External load vector

The stiffness matrix is assembled from individual element stiffness matrices derived from material properties (Young's modulus E), cross-sectional area A, and member length L. After applying displacement boundary conditions, the reduced matrix system is solved numerically using MATLAB.

Objectives:

1. To assemble equilibrium equations and solve using simultaneous linear equations.
2. To formulate the structural equilibrium equations in matrix form using the Direct Stiffness Method.
3. To assemble the global stiffness matrix from individual element stiffness matrices based on:

$$ke = \frac{AE}{L}$$

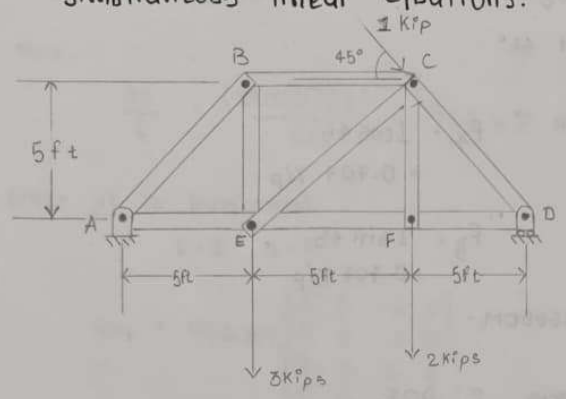
Assumptions:

1. Pin-Jointed Connections.
2. Axial Force Members Only.
3. Linear Elastic Material Behaviour.
4. Uniform Cross-Section.
5. Homogeneous and Isotropic Material.
6. Static Loading Condition.

Mathematical Modeling:

TRUSS JOINT FORCE ANALYSIS

OBJECTIVE - Assemble Equilibrium Equations and solve using simultaneous linear equations.



1. MEMBERS & JOINTS

AB, BE, BC, EC, CF, CD, AE, EF and FD are the 9 members of this Truss.

There are total Six joints; 4 bottom joints and 2 upper joints.

2. MATERIAL

The material for Truss is steel. It's modulus of elasticity is 29000 KSI.

↳ Diagonal Length -

$$L = \sqrt{5^2+5^2}$$
$$= 7.07 \text{ ft}$$
$$= 84.85 \text{ in.}$$

3. LOAD VECTOR

At E → 3 Kips (↓)

At F → 2 Kips (↓)

At C → 1 Kip at 45°

Resolving at C →

$F_x = 1\cos 45°$
$= 0.707$ Kip

$F_y = 1\sin 45°$
$= 0.707$ Kip

4. DEGREE OF FREEDOM.

Each joint has 2 DOF.

So,
Total DOF $= 6 \times 2$
$= 12.$

Joint	DOF_x	DOF_y
A	1	2
E	3	4
F	5	6
D	7	8
B	9	10
C	11	12

5. Element Stiffness Matrix Formula

$$K_e = \frac{AE}{L}\begin{bmatrix} c^2 & cs & -c^2 & -cs \\ cs & s^2 & -cs & -s^2 \\ -c^2 & -cs & c^2 & cs \\ -cs & -s^2 & cs & s^2 \end{bmatrix}$$

i. For Horizontal Member AE

$L = 5ft = 60in$

Now,

$$\frac{AE}{L} = \frac{(29000)(2)}{60} = 966.67 \text{ kip/in}$$

since it is horizontal

$C = 1 \quad S = 0$

$$K_{AE} = 966.67 \begin{bmatrix} 1 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 \\ -1 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

ii. Diagonal AB

$L = 84.85 \text{ in}$

$$\frac{AE}{L} = \frac{29000 \times 2}{84.85} = 683.55 \text{ kip/in}$$

$$C = \frac{60}{84.85} = 0.707$$

$$S = 0.707$$

$$K_{AB} = 683.55 \begin{bmatrix} 0.5 & 0.5 & -0.5 & -0.5 \\ 0.5 & 0.5 & -0.5 & -0.5 \\ -0.5 & -0.5 & 0.5 & 0.5 \\ -0.5 & -0.5 & 0.5 & 0.5 \end{bmatrix}$$

$$K_{AB} = \begin{bmatrix} 341.8 & 341.8 & -341.8 & -341.8 \\ 341.8 & 341.8 & -341.8 & -341.8 \\ -341.8 & -341.8 & 341.8 & 341.8 \\ -341.8 & -341.8 & 341.8 & 341.8 \end{bmatrix}$$

6. Boundary Conditions

Supports- A -> DOF 1 = 0

A -> DOF 2 = 0

D -> DOF 8 = 0

Reducing matrix by -> 12 - 3 = 9

$[K_r]_{9\times 9}$

7. Displacement Vector

after applying BC's we got,

$$U_r = \begin{bmatrix} u_3 \\ v_3 \\ u_5 \\ v_5 \\ u_7 \\ u_9 \\ v_9 \\ u_{11} \\ v_{11} \end{bmatrix} = \begin{bmatrix} u_E \\ v_E \\ u_F \\ v_F \\ u_D \\ u_B \\ v_B \\ u_C \\ v_C \end{bmatrix}$$

8. Load Vector

$$F_r = \begin{bmatrix} 0 \\ -3 \\ 0 \\ -2 \\ 0 \\ 0 \\ 0 \\ -0.707 \\ -0.707 \end{bmatrix}$$

9. Global Stiffness Matrix K_r (Reduced) -

$$K_r = \begin{bmatrix} 1933 & 0 & -966 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1367 & 0 & -341 & 0 & 0 & 0 & 0 & 0 \\ -966 & 0 & 1933 & 0 & -966 & 0 & 0 & 0 & 0 \\ 0 & -341 & 0 & 1367 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & -966 & 0 & 966 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 683 & 341 & -341 & -341 \\ 0 & 0 & 0 & 0 & 0 & 341 & 683 & -341 & -341 \\ 0 & 0 & 0 & 0 & 0 & -341 & -341 & 683 & 341 \\ 0 & 0 & 0 & 0 & 0 & -341 & -341 & 341 & 683 \end{bmatrix}$$

10. Final Matrix Equation

$$[K_r]_{9\times 9}\{u_r\} = \{F_r\}$$

By solving matrix, we get Displacement

$$v_E = -0.0112 \text{ in}$$
$$v_F = -0.0085 \text{ in}$$
$$v_C = -0.0051 \text{ in}$$

10. Computing Member Forces

$$F = \frac{AE}{L}[-c \ -s \ c \ s]\{u_e\}$$

* FINAL MEMBER FORCES

MEMBER	FORCE (Kips)	NATURE
AB	4.1	Compression
BE	2.9	Tension
BC	5.6	Compression
EC	4.8	Tension
CF	1	Tension
CD	4	Compression
AE	2.7	Tension
EF	3.2	Tension
FD	2	Tension

Results & Discussion:

1. Displacements

   The reduced global stiffness matrix was solved using MATLAB to obtain the nodal displacement vector. The computed displacements (in inches) are:

   - vE = -0.0112 in
   - vF = -0.0085 in
   - vC = -0.0051 in

   The maximum vertical displacement occurs at **Joint E**, which is directly subjected to the highest external load (3 kips). All displacement values are small, which validates the assumption of small deformation theory.

2. Structural Behaviour Interpretation:
   - Diagonal members like AB and BC are under compression, suggesting that the structure resists a vertical load through a compressive axial force.
   - Bottom chord members like AE, EF, and FD are under tension, suggesting that the structure resists a horizontal spreading force.
   - From the force distribution, it is clear that the loaded joints have successfully transferred the load to the supports.
   - Compression members are mostly located in the upper and inclined members, a phenomenon that is common in truss structures subjected to a downward force.

3. Numerical Method Validation:
   - The matrix equation [Kr][Ur]=[Fr][K_r][U_r] = [F_r][Kr][Ur]=[Fr] was solved using MATLAB.
   - Results are consistent with theoretical stiffness method formulation.
   - The structure behaves linearly, confirming correct assembly of the global stiffness matrix.

Conclusion:

- In the above case study, the equilibrium equations for the structure were successfully formulated and solved using simultaneous equations.
- The structural behavior was formulated using the matrix method under the Direct Stiffness Method. The global stiffness matrix was formulated from the stiffness matrices of the structural members.
- The matrix equations were solved using MATLAB. The results were consistent with the principles of structural mechanics. Thus, the objectives were met.
